See MPEP chapter 600 concerning utility patent application contents.

1. ☒ Fee Transmittal Form (e.g., PTO/SB/17)  
(Submit an original and a duplicate for fee processing)
2. ☐ Applicant claims small entity status.  
See 37 CFR 1.27.
3. ☒ Specification [Total Pages **38** ]  
(preferred arrangement set forth below)
  - Descriptive title of the invention
  - Cross Reference to Related Applications
  - Statement Regarding Fed sponsored R & D
  - Reference to sequence listing, a table, or a computer program listing appendix
  - Background of the Invention
  - Brief Summary of the Invention
  - Brief Description of the Drawings (if filed)
  - Detailed Description
  - Claim(s)
  - Abstract of the Disclosure
4. ☒ Drawing(s) (35 U.S.C. 113) [ Total Sheets **7** ]
5. Oath or Declaration [ Total Pages **3** ]
  - a. ☒ Newly executed (original or copy)  
Copy from a prior application (37 CFR 1.63 (d))  
(for continuation/divisional with Box 17 completed)
  - b. ☐ **DELETION OF INVENTOR(S)**  
Signed statement attached deleting inventor(s)  
named in the prior application, see 37 CFR  
1.63(d)(2) and 1.33(b)
6. ☐ Application Data Sheet. See 37 CFR 1.76

ADDRESS TO:

Assistant Commissioner for Patents  
Box Patent Application  
Washington, DC 20231

7. ☐ CD-ROM or CD-R in duplicate, large table or  
Computer Program (Appendix)
8. Nucleotide and/or Amino Acid Sequence Submission  
(if applicable, all necessary)
  - a. ☐ Computer Readable Form (CRF)
  - b. Specification Sequence Listing on:
    - i. ☐ CD-ROM or CD-R (2 copies); or
    - ii. ☐ paper
  - c. ☐ Statements verifying identity of above copies

**ACCOMPANYING APPLICATION PARTS**

9. ☒ Assignment Papers (cover sheet & document(s))
10. ☐ 37 CFR 3.73(b) Statement ☒ Power of  
(when there is an assignee) Attorney
11. ☐ English Translation Document (if applicable)
12. ☐ Information Disclosure ☐ Copies of IDS  
Statement (IDS)/PTO-1449 Citations
13. ☐ Preliminary Amendment
14. ☒ Return Receipt Postcard (MPEP 503)  
(Should be specifically itemized)
15. ☐ Certified Copy of Priority Document(s)  
(if foreign priority is claimed)
16. ☐ Other: .....

17. If a CONTINUING APPLICATION, check appropriate box, and supply the requisite information below and in a preliminary amendment, or in an Application Data Sheet under 37 CFR 1.76:

☐ Continuation ☐ Divisional ☐ Continuation-in-part (CIP)

of prior application No. \_\_\_\_\_ / \_\_\_\_\_

**SWITCH-BASED ACCELERATION OF COMPUTER DATA STORAGE  
EMPLOYING AGGREGATIONS OF DISK ARRAYS**

Inventors: George Ericson; Robert Solomon; Jeffrey Brown; John Haynes

Attorneys:

Joel Wall, Esq.  
P.O. Box 169  
Hopkinton, MA 01748  
508-435-4432

**SWITCH-BASED ACCELERATION OF COMPUTER DATA STORAGE  
EMPLOYING AGGREGATIONS OF DISK ARRAYS**

**FIELD OF THE INVENTION**

The present invention relates generally to computer data storage systems and, more particularly, relates to acceleration of computer data storage utilizing fibrechannel switches, disk drive aggregators, and arrays of disk drives.

**BACKGROUND OF THE INVENTION**

Computer systems are pervasive in our society and virtually all human activity is now influenced at least to some extent by existence and usage of these systems. The faster and more efficient these systems are, the better for all concerned. Certain computer systems developing within the technological area known as fibrechannel or fibrechannel networks do offer faster and more efficient operation, not only because of their optically-communicative capability but for other reasons as well. One of the configurations in fibrechannel networks employs multiple disk drive arrays for data storage managed by an aggregator (essentially another array but with much higher intelligence than ordinary arrays and which organizes ordinary arrays into "aggregations") in combination with a fibrechannel switch (another intelligent device which performs a complex switching function under control of at least the aggregator). Typical inter-relationships of computer, aggregator, switch, and storage within fibrechannel networking have been established.

Referring to Fig. 1, there is depicted one typical fibrechannel computer system arrangement. Computer hosts 101, 102, and 103 communicate through fibrechannel switch or hub 104, sometimes known as a “fabric”. The term “fabric” suggests densely-packed multiple conductors, since internal fibrechannel switch connections can be very dense. The irregularly-shaped “cloud” symbol representing the switch implies an active or changeable entity which is capable of being used or controlled. Front end fabric 104 connects to aggregator 105 (typically a RAID system, standing for Redundant Array of Independent/Inexpensive Disks) which, in turn, connects to back end fabric 106 (another fibrechannel switch or hub) to which are connected multiple disk drives 107, 108, 109, and 110. A major goal of this system is efficient movement of data or computer information from hosts to disk drive storage and vice-versa. If all computers communicate directly with all disk drives (and there can be many more than three hosts and four drives, those numbers being represented here only for purposes of clarity of illustration) then highly complex and inefficient operation with multiple hosts competing for the same storage space on the same disk drives, etc. can result. Thus, an aggregator is used to allow communication by computers with drives, but only through the aggregator to improve operation. The aggregator is a highly intelligent and complex device which appears to computers such as hosts 101, 102, and 103 to be a number of disk drives. The aggregator further appears to the computers to be the only disk drives in the system since it “hides” disk drives 107 - 110 connected to the back end fabric. This reduces complexity for computer hosts to a great extent. Further, this introduces a degree of security since all commands relative to data stored on disk drives from hosts must pass through, and thus be “approved” by, the aggregator. Any illegitimate command or

1 operation may be stopped by the aggregator before it does damage. But, unfortunately,  
2 the aggregator can become a bottleneck in this configuration between computers and disk  
3 drives under certain high-traffic or busy or other conditions. Thus, the aggregating  
4 device can introduce "latency" or time delay into system operation and contribute to the  
5 very inefficiencies in system operation that it was designed to reduce or eliminate. Under  
6 certain circumstances, this can be a serious problem.

7       However, if the back end drives were directly accessible via the front end fabric,  
8 the aggregation "bottleneck" would be removed and certain reductions in these latencies  
9 might be achieved. In Fig. 2, Host computers 201, 202, and 203 are shown connected to  
10 front end fabric - fibrechannel switch 204 to which are also connected aggregator 208 and  
11 disk drives 205, 206, and 207. It is to be understood that the number of hosts and drives  
12 are not limited to the specific number shown and that many more, or fewer, hosts and  
13 drives are intended to be represented by this diagram. In operation, any one or more of  
14 the hosts first sends data requests to the aggregator which then enables the disk drives  
15 and alerts them that these requests are coming directly to any one or more of them. Then  
16 hosts send multiple requests addressed to the disk drives through the switch *directly* to  
17 these different drives, accessing these drives in parallel and receiving *directly* back  
18 multiple data streams in parallel through the switch, which reduces the latency factor by  
19 eliminating at least one "hop" through the aggregator. However this configuration re-  
20 introduces the security issue, because these drives, not being "protected" by the  
21 aggregator, are more exposed to illegitimate commands in this configuration. Thus, disk  
22 drives and computers in this configuration have to contain added intelligence to deal with

1 these security issues and the task of adding this intelligence creates a more complicated  
2 and less desirable environment.

3 Referring next to the subject of fibrechannel protocols as further useful  
4 background information, a book entitled "Fibre Channel Volume 1 The Basics" by Gary  
5 R. Stephens and Jan V. Dedek, published by Ancot Corp, Menlo Park, California, first  
6 edition June, 1995, is incorporated by reference herein. Within the computer industry  
7 there are highly competitive companies which specialize in design, development and  
8 manufacture of these switches, aggregators, memory arrays, and other fibrechannel-  
9 related components. If their respective designs are to be employed in the same system, or  
10 if multiple systems employing their various designs are networked together, these designs  
11 have to mesh together properly for users to derive any benefit from them. This is  
12 accomplished by having these companies agree to certain standards sometimes  
13 generically known as the "ANSI Fibre Channel Standard". These standards are complex  
14 and are negotiated into existence by the very companies that are responsible for creating  
15 these fibrechannel-related components. One of the agreedupon products of these  
16 negotiations is what is sometimes called the "protocol stack"-- five network levels of  
17 fibrechannel. (In computer networks, information or data sent between network devices  
18 is conducted on a physical level normally by electrons or photons over copper wires or  
19 fibre-optic paths respectively, and/or by telecommunication paths, and, at the same time,  
20 is also *virtually* conducted on multiple other network levels above the physical level.)  
21 Referring to Fig 3A, five levels: FC-0, FC-1, FC-2, FC-3 and FC-4 are shown,  
22 corresponding to: physical, encode/decode (8B/10B), Framing Protocol, Common  
23 Services for Ports, and Mapping respectively. {Sometimes, another sixth layer, Upper

1 Layer Protocol, is referred to, and is shown.} Briefly, the FC-0 functional level relates to  
2 physical connection of nodes, either optical or electrical – the nuts and bolts of  
3 connection. The FC-1 functional level relates to how information is transmitted between  
4 fibrechannel input/output ports, i.e. how lasers and electrical drivers/receivers deal with a  
5 bit stream moving into and out from a fiber. The FC-2 functional level deals with  
6 transferring information and is concerned with its content, proper arrival of content or  
7 detection of missing information or information errors; this level thus defines frame fields  
8 including frame header field layout and is utilized in embodiments of the present  
9 invention. The FC-3 functional level deals with common services that can be shared  
10 among ports. And, the FC-4 functional level handles mapping of existing non-  
11 fibrechannel I/O interfaces for use on fibrechannel by using fibrechannel tools.

12 The foregoing latency problem of the prior art is addressed and relieved, without  
13 reducing security, by the welcome arrival of the present invention which operates not  
14 only within parameters of the ANSI Fibre Channel Standard, but, as suggested, makes  
15 novel use of fibrechannel level FC-2, as described hereinbelow.

16

17

### SUMMARY OF THE INVENTION

18

19

20

21

22

23

The present invention in a broad aspect relates to a network-attached storage computer system having disk drives and an aggregator attached to the network. Direct or indirect data transfer between computer and disk drives is determined by its impact on overall performance of the system. If determined that indirect transfer would increase overall system performance compared to direct transfer, data is sent between computer and disk drives through the network *and* through the aggregator. If determined that direct

1 transfer would increase overall system performance compared to indirect transfer, data is  
2 sent between computer and disk drives through the network but *not* through the  
3 aggregator.

4 The present invention in another aspect relates to a computer data storage system  
5 wherein data is grouped in frames. There are disk drives or the like for storing and  
6 retrieving data and an aggregator or data storage manager for managing operation of the  
7 disk drives. Each of the frames includes a frame header which designates parameters  
8 associated with data in its frame. One of the parameters is destination ID (identity of the  
9 destination). There is a controllable switch connected between computer, disk drives,  
10 and aggregator for selecting certain frames and flowing data in those selected frames  
11 directly between computer and disk drives. The aggregator is destination ID in the  
12 selected frames, but transfer of data in the selected frames between computer and disk  
13 drives is direct and not through the aggregator. Thus, latency issues can be reduced or  
14 eliminated because of direct flow of data between computer and disk drives, while at the  
15 same time not reducing security since the destination ID for data in the selected frames  
16 remains the aggregator.

17 In a further feature of the present invention, the switch includes switch control  
18 logic under command of the aggregator to select those frames to be transferred directly.  
19 The switch control logic includes a frame header field selector such as a frame header  
20 mask, an input frame header buffer, and a map table.

21 In yet another aspect, the present invention is incorporated in a computer system  
22 including both disk drives or the like for storing and retrieving data grouped in frames  
23 and an aggregator normally in the path of the frames flowing between computer and disk

1 drives. The present invention employs computer logic and relates to enhancing transfer  
2 of data between computer and disk drives. This involves establishing a frame header  
3 field selector such as a mask containing only relevant information. The frames including  
4 their respective headers are received from the computer, and headers and mask are  
5 compared to obtain “distilled” frame headers. A map table is established which contains  
6 sets of frame header fields corresponding to input addresses (proxy destination IDs) of  
7 the disk drives. The map table is searched to find matches between distilled frame  
8 headers and sets of frame header fields. For each match, a proxy destination ID is  
9 substituted in place of the original destination ID in headers of each of the corresponding  
10 frames which are then forwarded directly to the disk drives and not via the aggregator.  
11 This data transfer enhancement operation is not perceptible by the host computer.

12 And in yet another aspect, the present invention relates to a computer program  
13 product for use in a computer system employing network-attached storage having both  
14 disk drives and a disk drive aggregator attached to the network. There is included a  
15 computer usable medium having computer readable program code thereon for enhancing  
16 the transfer of data between the computer and the disk drives.

17 It is thus advantageous to use the present invention to reduce latency issues  
18 without negatively impacting data security in a network-attached-storage-based computer  
19 system.

20 It is a general object of the present invention to provide increased overall system  
21 performance in a computer system.

1           If is a further object of the present invention to provide improved performance in  
2 storage and retrieval of data in a computer system, including a network-attached-storage  
3 computer system.

4           It is an additional object of the present invention to provide apparatus and  
5 methodology for allowing direct data flow between a computer system's host computers  
6 and disk drives under certain conditions while maintaining data security.

7           It is a still further object of the present invention to provide an improved  
8 fibrechannel-based computer system employing multiple disk drives wherein latency  
9 normally introduced by bottleneck-operation of an aggregator is reduced or eliminated.

10          Other objects and advantages will be understood after referring to the detailed  
11 description of the preferred embodiments and to the appended drawings wherein:

12

13                           **BRIEF DESCRIPTION OF THE DRAWINGS**

14          Fig. 1 is a diagram of a prior art arrangement of host computers, fibrechannel  
15 switches, aggregator, and disk drives;

16          Fig. 2 is a diagram of another prior art arrangement of host computers,  
17 fibrechannel switch, aggregator, and drives;

18          Fig. 3A depicts the fibrechannel levels with their respective designations;

19          Fig. 3B depicts a layout of a typical frame in accordance with fibrechannel level  
20 FC-2;

21          Fig. 3C depicts a layout of at least a portion of the fibrechannel level FC-2 frame  
22 header of Fig. 3B;

Fig. 4 is a schematic diagram of a write command processed in accordance with an embodiment of the present invention;

Fig. 5 is a flowchart depicting the algorithmic process performed by the embodiment of the present invention of Fig.4;

Fig. 6 depicts a map table listing certain sets of frame header fields associated with their respective proxy destination IDs;

Fig. 7 is a schematic diagram of the switch of Fig. 4 showing its switch control logic including the map table of Fig. 6 under command of the aggregator of Fig. 4; and,

Fig. 8 is a schematic diagram of a read command processed in accordance with an embodiment of the present invention.

## DESCRIPTION OF THE PREFERRED EMBODIMENTS

### Figure 3B

Referring to Fig. 3B, a typical fibrechannel frame in accordance with level FC-2 of the fibrechannel protocol stack is shown. This frame contains multiple fields which normally contain predetermined ranges of bytes. Typically the opening “idles” field has six transmission words or 24 bytes; “start of frame” (SOF) field has one transmission word or four bytes; the “header” field has six transmission words or 24 bytes and is of primary interest because it relates to the present invention and contains information about its frame’s contents or purpose, somewhat analogous to ID/origin/destination information displayed on a human-transit bus above the bus driver’s windshield; the “optional headers and payload” field can be the largest field ranging from zero to 528 transmission words or 2112 bytes; “cyclic redundancy check” (CRC) and “end of frame” (EOF) fields

are each one transmission word of four bytes each; and closing “idles” field is again six transmission words or 24 bytes.

### Figure 3C

Referring to Fig. 3C, the frame header of Fig. 2 is expanded to show the five words of interest in this header, the number of bytes per header (four) and various fields associated with particular bytes. The header actually contains six words. Starting at the left-hand side, R\_CTL is “routing control” represented by byte zero. D\_ID is “destination identity” represented by bytes 1-3. Byte 4 is not used. S\_ID is “source identity” and is designated by bytes 5-7. Byte 8 is “type”. F\_CTL is “frame control” and is designated by bytes 9, A, B. SEQ\_ID is “sequence identity” and is byte C. DF\_CTL is “data field control” and is byte D. SEQ\_CNT is “sequence count” and is designated by bytes E and F. OX\_ID is “originator’s identity” and is designated by bytes 10-11. Finally, RX\_ID is “receiver’s identity” and is designated by bytes 12-13. The D\_ID, S\_ID, and OX\_ID fields in this header are utilized by embodiments of the present invention. Other fields may also be used and are selected by the frame header field selector such as a mask or its equivalent. These specific fields and these other fields shall be described more fully hereinbelow.

### Figure 4

Referring to Fig. 4, a schematic block diagram of a computer system operating in accordance with an illustrative embodiment of the present invention is presented. Host computer 401 is labeled “I” for “initiator”; fibrechannel switch 402 is identified and shown as a box rather than a cloud only for purposes of convenience of illustration; aggregator 403 is labeled “A”; memory array or disk drive group 404 is labeled “Z”, and

1 memory array or disk drive group 405 is labeled "Y". These system components are  
2 shown as being interconnected by communication paths which are syntactically identified  
3 for purposes of ease of description. The syntax is as follows:

4 Command N(S\_ID, D\_ID, OX\_ID)(Proxy x\_ID, x)

5 where "Command" is either a "read" from or "write" to memory with respect to host 401,  
6 "N" is a number representing communication count in this particular group or exchange  
7 of communications, "S" represents source of the command, "D" represents destination of  
8 the command, "OX" represents originator's exchange, "Proxy x" represents a substituted  
9 source or destination command where "x" represents either substituted source S or  
10 substituted destination D, and "ID" stands for the respective component's identity in each  
11 case.

#### 12 Write Command Operation

13 In operation, host computer 401 issues a write request or command with syntax  
14 label W1(I,A,1) which stands for: W = Write command; 1 = this is the first  
15 communication in this particular exchange of communications designated "1" and  
16 pertaining to this Write command; (I = S\_ID; A = D\_ID; 1 = OX\_ID). Switch 402  
17 receives W1(I, A, 1) at one of its input ports (not shown in this Fig.) and transfers it  
18 through to aggregator 403 via communication path syntactically labeled W2(I,A,1) which  
19 is essentially a continuation of W1(I,A,1). In response to W2(I,A,1) aggregator 403  
20 issues two commands: a mapping command and a proxy write command. Map command  
21 M3(I,A,1)(Z,D) is forwarded to switch 402 over command input port 406 where it  
22 commands a mapping function within the switch (to be discussed below). Proxy write

1 command PW4(A,Z,1)(I,S) is also forwarded to switch 402 where it is switched to disk  
2 drive Z via the line syntactically labeled PW5(A,Z,1)(I,S).

3 Before proceeding further with the syntactical narrative of Fig. 4, consider what  
4 has been thus far represented: A write request is issued by the host computer – it wishes  
5 to write data into a disk drive. It sends the request to the aggregator (via the switch)  
6 which is in charge of efficiently managing disk drive resources available to the computer.  
7 Upon receipt of this write request, the aggregator not only “decides” that this request  
8 should be directed to disk drive Z rather than disk drive Y, but also “decides” that it  
9 would be in the system’s best interests if future communications from Host 401 with  
10 respect to this particular write request *not* proceed through the aggregator. Therefore, the  
11 aggregator issues a map command to the switch to generate a frame header mask and a  
12 map table (both shown in Fig. 7 and to be discussed below) for purposes of diverting  
13 certain future communications from initiator 401 to substitute or proxy destination disk  
14 drive Z (also to be discussed in detail below). The aggregator further issues a Proxy  
15 write command PW4(A,Z,1)(I,S) to communicate to disk drive Z a proxy or substitute  
16 source ID, namely that of initiator “I” rather than its own ID. Accordingly, at this point  
17 in the communication proceedings for this write command, (1) the switch has been  
18 commanded to forward future communications from I for this write command having  
19 “A” as destination, from I *directly* to disk drive Z without proceeding through A, and (2)  
20 disk drive Z has been “advised” or commanded to substitute initiator “I” as the source for  
21 write requests which arrive at Z actually by way of A.

22 Returning, now, to the syntactical description of Fig. 4, disk drive Z responsive to  
23 proxy command PW5(A,Z,1)(I,S) issues a transfer ready signal or command identified as

1 X6(A,I,1) which is interpreted as follows: “X” means transfer; “6” is the number  
2 corresponding to this sixth communication step in the same originator’s exchange  
3 process; (source ID is A; destination ID is I; and this is still the same Write request  
4 identified by originator’s exchange “1”). This transfer ready command goes through  
5 switch 402 and via the communicative link syntactically identified as X7(A,I,1) is  
6 transferred to its destination, Initiator I, “advising” initiator I that conditions are ready for  
7 data to be written. Initiator I, responsive to this transfer ready command, sends data to  
8 switch 402 via the communicative link syntactically identified as D8(I,A,1), which stands  
9 for: data, the eighth step count in this process, (source is I, *destination is A*, and same  
10 write request #1) respectively. The destination was italicized in the prior sentence to  
11 emphasize that A shall not receive this data despite destination “A” being designated in  
12 the syntax because of map conditions earlier established in the switch (which will be  
13 discussed below). In response to the map operation in the switch to be described below,  
14 the switch detects a match involving disk drive Z and certain frame header elements,  
15 substitutes disk drive Z for aggregator A 403 in the header’s D\_ID field, and sends this  
16 data *directly* to disk drive Z via communicative link identified by D9(I,Z,1). Disk drive Z  
17 then completes the proxy write command by issuing back to aggregator A a status signal  
18 identified as S10(Z,A,1) where Z is source, A is destination, etc. This status signal goes  
19 through the switch and via the link identified by S11(Z,A,1) from the switch to A where  
20 it provides a status report to A that the write was successfully completed. At this point, A  
21 can dismantle or neutralize the map table it established in the switch, whereupon it issues  
22 an “unmap” command UM12(I,A,1) to the switch and the map table is dismantled  
23 whereby its operational effect is neutralized.

1           In other words, in the last paragraph and the operation of Fig. 4 thus far, it should  
2   be understood that the transfer ready signal advised the computer that conditions are  
3   ready for data to be transferred, and that the computer sent the data addressed to the  
4   *aggregator A*, via D8(I,A,1). Because of the switch's intelligence it "decided" to not  
5   allow this write command to flow to the aggregator, and diverts it by way of the map  
6   table directly to disk drive Z on link identified as D9(I,Z,1). After the status report is  
7   made from the disk drive via the switch to the aggregator, the aggregator decides to  
8   dismantle the map table which it no longer needs for this particular write command, via  
9   unmap command UM12(I,A,1).

10           It can be seen that *all* destination ID's for host-originated commands are the  
11   aggregator A, as in (note the bold emphasis) W1(I,A,1) and D8(I,A,1), and, *all* source  
12   ID's for host-received commands are aggregator A, as in (again note bold emphasis)  
13   X7(A,I,1) and S14(A,I,1). These results obtain even though the transfer ready command  
14   originates on disk drive Z and not A and even though the data command causes data to be  
15   written into disk drive Z and not A. Therefore, *from the host's viewpoint, nothing has*  
16   *changed with respect to the switch or the aggregator with which it is connected!* This  
17   entire proxy operation in redirecting commands directly to specific disk drive  
18   components is not perceptible by the host.

19           All commands and signals except for possibly the map/unmap and proxy  
20   commands are standard fibrechannel level FC-2 compatible commands. Accordingly,  
21   since the syntax of all information transmitted in Fig. 4 (except for possibly map/unmap  
22   and proxy commands) is solely reflective of fields in the frame header, all such  
23   information with possible exceptions noted can fit within the frame header. This

embodiment of the present invention takes advantage of the potential afforded by the frame header to insert proxy commands into the header to achieve this important result in latency reduction. Typically, map/unmap commands can be fabricated at the SCSI (small computer system interface) level, or could be at the microcode level in assembler language; alternatively, they can also be FC-2 compatible. In any case, they would be compatible with the fibrechannel switch internals. Furthermore, the proxy commands are proprietary SCSI upper level protocol commands which map to SCSI lower level protocol commands, which are, in turn, mapped onto communications media dependent protocols such as the FC-2 protocol layer.

All write command activity shown in Fig. 4 was executed with respect to disk drive Z because of a decision made by the aggregator to use disk drive Z. However, it could have selected disk Y or, alternatively, could have decided to alternate host-initiated write and/or read commands between disk drives Z and Y (and any other disk drives in the system not shown in this Fig.) and permit the system to process these commands virtually in parallel. In the latter alternative case the map operation(to be discussed below) could be extended to include sequence count and sequence ID information from the frame header where the map operation would be more complex. Such syntax would take the following form:

Map(S\_ID, D\_ID, OX\_ID, SEQ\_ID, SEQ\_CNT)[(Proxy x\_ID), x]

where all items have been previously identified.

#### **Figure 8 – Read Command Operation**

A read command example would be similar to the write command example shown, but a map command is not needed because the switch does not need to be

1 involved in the proxy operation for read commands. The transfer ready command is also  
2 not needed in a read example because the relationship between (initiator) host computer  
3 and (target) disk drive is that the latter drives the sequencing. The host initiator is  
4 assumed to be ready, since it initiated the read request. So after the read request is issued,  
5 whenever the (target) disk drive is ready to send data, it does. Referring to Fig. 8, there is  
6 presented the same schematic block diagram of a computer system as used in Fig. 4, and  
7 employing the same syntax, but where disk drive Y, drive 405, is used in this read  
8 example instead of reusing disk drive Z, drive 404, for purposes of clarity of presentation.  
9 As in the write example, Initiator 401 forwards a read command syntactically identified  
10 as R1(I,A,2) with the usual meaning: R = a read request, 1 = the first command in this  
11 series, (I = Initiator is the source of the command, A = Aggregator is the destination of  
12 the command, and 2 = the second originator's exchange). This read request flows  
13 through the switch and via a link identified syntactically as R2(I,A,2) is received by  
14 aggregator 403. The aggregator responds by turning the read command into a proxy read  
15 request: PR3(A,Y,2)(I,S) which travels through the switch to disk drive Y via the link  
16 identified by PR 4(A,Y,2)(I,S). In this proxy command, PR = proxy read; 4 = the fourth  
17 command of this originator's exchange; (A = actual source aggregator; Y = actual  
18 destination disk drive Y; 2 = second originator's exchange)(I = Initiator as the proxy; and  
19 S = "Source", meaning that the aggregator is identifying or substituting the proxy  
20 Initiator in the role of source to disk drive Y). Disk drive Y retrieves the data from  
21 within its storage and delivers it to the switch over the link identified by syntax:  
22 D5(A,I,2), where, as reflected by "A" being in the source position of the syntax, disk  
23 drive Y is responding in the role of aggregator as source of the data command thus

1 conforming itself to the appropriate component that would have just received a command  
2 from the Initiator, namely, the aggregator. The switch forwards the data to I via the link  
3 identified by D6(A,I,2). (Note that “A” is still designated the source although “Y” is the  
4 actual source of this data.) Drive Y issues a status confirmation via link identified by  
5 S7(Y,A,2) through the switch and via the link identified by S8(Y,A,2) to the aggregator.  
6 The aggregator issues a status confirmation to the Initiator via the link identified by  
7 S9(A,I,2) through the switch and via the link identified by S10(A,I,2) to the initiator. The  
8 major difference(s) between this read example and the prior write example is that the  
9 switch does not need to redirect any commands in the read example. Therefore the map  
10 command is not needed (and thus the unmap command is not needed).

11 Focusing on the proxy read command **PR3(A,Y,2)(I,S)** or its continuation  
12 **PR4(A,Y,2)(I,S)** and the responsive data command D5(A,I,2) or its continuation  
13 D6(A,I,2), the significance of the functionality expressed by the syntax should not be  
14 overlooked. These commands mean that the *aggregator* (which would have otherwise  
15 been the source with respect to disk drive Y in an ordinary read command) is sending this  
16 *read* command to the *disk drive Y* (which would have otherwise been the destination with  
17 respect to the aggregator in an ordinary read command) and is herewith syntactically  
18 identified within the proxy command **PR3(A,Y,2)(I,S)** in bold italics. But, this command  
19 is a proxy command and is thus sending *additional* information identified in the proxy  
20 portion of the command “**PR3(A,Y,2)(I,S)**”, again in bold italics. The additional  
21 information is a request to *substitute the initiator as the source of this command*. This  
22 complete proxy command is received by Disk drive Y which *cooperates* and makes that  
23 substitution. The result of this cooperation is observable in the responsive data command

1 output by disk drive Y. Disk drive Y sends the data *not* back to A, the actual source of  
2 the command, but to I, the proxied or substituted source of the command, *and identifies*  
3 *itself in the data command as aggregator A*. Examining the syntax for the data command  
4 one observes that *the aggregator is in the position of the source, and the initiator is in the*  
5 *position of the destination*. The net effect of these substitutions is that: (1) an additional  
6 hop through the aggregator is avoided when data is forwarded from a disk drive  
7 responsive to a read request from the initiator – data goes directly to the initiator (albeit  
8 through the switch or network) from the drive rather than (again via the switch) back  
9 through the aggregator from which the command actually was received, and (2) the host  
10 initiator is not impacted since the commands it sends and receives do not suggest  
11 anything other than what the host had expected – requests made by and directed from the  
12 initiator host to the aggregator as a destination, and data received by the host initiator  
13 from the aggregator as a source! Thus, “the host is not in the game”, using a colloquial  
14 expression to highlight the fact that other components or sub systems in this overall  
15 network attached storage system are cooperating or conspiring in a manner to improve  
16 throughput and improve other system performance characteristics without the host being  
17 aware of these changes, or substitutions, or proxies. And, as noted with the earlier-  
18 discussed write example, this entire proxy operation is not perceptible by the host.

### 19 **Figure 5**

20 Referring next to the flowchart of Fig. 5, it depicts the algorithmic process  
21 inherent in operation of switch 402 in the computer system of Fig. 4 for the write  
22 command example illustrated. An input frame header (including its complete frame for  
23 which the header is identifying information) from the host computer enters an input port

1 on the switch in block 501. It is to be understood that there can be multiple hosts each  
2 sending write and/or read commands to this complex switch on its multiple input ports  
3 essentially simultaneously, and the switch under control of its aggregator shall be able to  
4 process all inputs appropriately. (This singular example of a write command is hereby  
5 disclosed for purposes of enhancing clarity of presentation and understanding of  
6 operation of the present invention. The corresponding flowchart for the read example  
7 would be less complex than this because there is no map table operation associated with  
8 the read command.) The algorithmic process moves to block 502 wherein a logical  
9 “AND” is performed between the input frame header received and a frame header field  
10 selector such as a frame header mask. The mask (more detail of which is presented  
11 below in connection with Fig. 7) is a template allowing only information relevant to this  
12 process. In other words, there are fields in the fibrechannel FC-2 frame header that may  
13 contain information irrelevant to operation of the present invention, and they are filtered  
14 out. The result of this logical “AND” step is information equal to or less than the mask  
15 information, i.e. a subset of the mask information termed a “distilled frame header”.  
16 The algorithmic process moves then to decision block 503 wherein the query is  
17 presented: is there an entry (i.e.: a set of frame header fields) in the map table matching  
18 the distilled frame header? This map table, earlier referred to in connection with  
19 description of Fig. 4 and to be described in more detail in connection with Fig. 7  
20 hereinbelow, is a dynamic table established in the switch. If the answer is “no”, the  
21 process moves to block 506 which routes the entire frame associated with the distilled  
22 frame header to the destination identified by the original D\_ID value in the header, which  
23 is a particular output port on the switch and the process is done. On the other hand, if the

1 answer is “yes”, then there is a match between the distilled frame header and a particular  
2 frame header entry in the map table and the algorithmic process moves to block 504  
3 where a substitution takes place. The particular D\_ID value corresponding to the  
4 matching entry (set of fields) in the table is substituted into the D\_ID field in the input  
5 frame header in place of the original value thus obtaining a “proxy” frame header. In  
6 other words, the result of this operation is a changed input frame header associated with  
7 the write command, this change taking place within the switch: the frame header was first  
8 “distilled” whereby irrelevant header information for this process was removed, and then  
9 the input frame header had its destination changed to this proxy destination. (In  
10 summary, Proxy D\_ID replaces the header field D\_ID and Proxy S\_ID replaces the  
11 header field S\_ID when they are used.) The algorithmic process moves next to block 505  
12 where the complete input frame, for which the proxy frame header is its identification, is  
13 routed to a *different* particular output port on the switch corresponding to the proxy frame  
14 header’s D\_ID value and the process is done. This means that data associated with this  
15 write command will be sent to a destination different from that originally intended,  
16 namely *directly* to a disk drive rather than the aggregator, and this change will take place  
17 within the switch.

### 18 Figure 6

19 Referring next to Fig 6, map table 600 is presented. This is a table which exists  
20 dynamically in fibrechannel switch 402. In other words, this table can be created, table  
21 entries can be changed, and the table can be deleted by operation of hardware, firmware,  
22 and/or software in the switch and controlled by the switch which is, in turn, controlled by  
23 aggregator 403. More detail on this operation will be given with respect to Fig. 7

1 hereinbelow. The table shown has two main columns, the one on the left being sets of  
2 Frame Header Fields and the other on the right being Proxy D\_ID's. In the Frame  
3 Header Fields column are sub columns for S\_ID, D\_ID, and OX\_ID. More sub columns  
4 could be entered as may be needed, as for example, entering SEQ\_ID and SEQ\_CNT to  
5 accomodate the disk Z/disk Y alternating scheme described earlier where sequence  
6 identity and sequence count are additional fields needed to implement the alternating  
7 scheme. Furthermore, this particular table as depicted contains entries that are reflective  
8 of the write operation described in connection with Fig. 4 and Fig. 5. The first row, for  
9 example, shows a set of earlier discussed values for S\_ID, D\_ID and OX\_ID being  
10 associated with a Proxy destination ID known as D\_ID"a". Other sets of entries in the  
11 table may show different values for S\_ID reflective of multiple computer hosts (up to "n"  
12 computer hosts) and different values for OX\_ID reflective of multiple write commands  
13 per host (up to "M" number of originator's exchange write commands with computer  
14 host "1", up to "N" number of originator's exchange write commands with computer host  
15 "2", and up to "P" number of originator's exchange write commands with computer host  
16 "n"). Each of these sets of entries is associated with a particular destination ID as  
17 suggested by the column heading, e.g. a particular disk drive. Thus this column under  
18 Proxy D\_ID's contains a range of destination IDs running; from D\_ID"a" to D\_ID"zzz"  
19 as shown. This nomenclature is intended to be suggestive of a large number of  
20 destination IDs and no particular fixed or limited number is intended to be represented  
21 hereby. Each of these destination IDs necessarily maps to a particular output port on the  
22 switch which connects to an appropriate disk drive. More discussion about this table will  
23 be provided in connection with Fig. 7.

**Figure 7**

Referring next to Fig. 7, switch 402 is shown with input ports 703, output ports 704 and 705, and containing, among other things, its switch control logic 700. Among other logic components not shown, switch control logic contains map table 600, frame header field selector or mask 701 and input frame header buffer 702. Map table 600 is the table described in Fig. 6. Header mask 701 and buffer 702 are dynamic constructs which can be implemented or dismantled, and are fashioned from computer hardware, firmware, and/or software within and/or related to the switch. Aggregator 403 commands control logic 700 by way of control port 406. Those skilled in the art and familiar with fibrechannel switches will appreciate how such control logic may be implemented from hardware, firmware and software.

In operation, if a write command is forwarded by a host to switch 402, it enters on one of input ports 703. This command is a full frame in fibrechannel protocol as shown in Fig. 3B. As it enters the switch, its header field as shown in Fig. 3C is loaded into header buffer 702, and if there is no prior-established proxy condition where there is no proxy match, the full frame is conducted to aggregator 403. Aggregator 403, as an overseer or manager for multiple disk drives, is aware of the state of activity and traffic regarding all of its disk drives, and makes a decision regarding if it would be in the computer system's overall best interest to (1) have this write command pass through itself to the disk array and then have such command's associated data also pass through itself on its way to the disk drive array, or (2) arrange for a proxy ID so that such data shall pass from the host computer into the switch and then written *directly* into the disk to avoid a bottleneck in the aggregator. Assuming the aggregator decides for a proxy ID, it

1 sends a map command via control port 406 to switch 402 which requests the switch to  
2 fabricate input header mask 701. The aggregator signals to the switch in this command  
3 precisely what elements should be put into the mask based on existing conditions and on  
4 the requirement of handling a write command from the host. Additionally, the aggregator  
5 also had commanded the switch control logic in this map command to fabricate map table  
6 600 with specific frame header field sets of entries with their corresponding proxy  
7 destinations based on existing conditions and on the requirement of handling a write  
8 command. Thereupon, the aggregator commands the switch control logic to compare the  
9 distilled header mask with the frame header field map table's sets of entries to seek a  
10 match and to select the Proxy D\_ID associated with that matched entry set as the new  
11 switch destination ID for data to be sent by the computer and to be written into the disk  
12 drive array. Accordingly, when data is sent by the host [syntax D8(I,A,1) in Fig. 4] to  
13 aggregator 403 responsive to a transfer ready command from the specified disk drive  
14 [syntax X6(A,I,1)] it first goes to the switch and then by prearranged proxy just described  
15 goes directly to disk drives and not to the aggregator.

16 Those skilled in this art including those directly connected with design and  
17 development of fibrechannel switches will recognize the fact that implementation of  
18 illustrative embodiments of the present invention is within their skills and expertise and  
19 will utilize appropriate hardware, firmware, and software to generate the logic to  
20 accomplish these implementations. For example, a typical host computer which can be  
21 used in connection with the present invention is any Intel, Sun Microsystems, Hewlett  
22 Packard or other similar company's computer using a fibrechannel host bus adapter with  
23 fabric support. A typical fibrechannel switch which might be used in connection with the

1 present invention and which can be fully implemented for Map/Unmap operations can be  
2 obtained from companies such as Brocade, McData, Vixel, or Ancor, etc. Typical disk  
3 drives which can be used in connection with the present invention are: any fibrechannel  
4 disk drive modified to support proxy read and proxy write. The frame header buffer, map  
5 table, frame header mask, and map/unmap commands would typically be implemented by  
6 combination of software and hardware in or related to the switch. Aggregator 403 can  
7 typically be derived from EMC CLARiiON model nos. 4700 which could have the  
8 capabilities called for herein. Furthermore, the specific illustrative embodiments  
9 presented are not the only ways of fabricating the present invention. For example, other  
10 ways of utilizing a fibrechannel switch to accomplish the goals of the present invention  
11 include use of hash table lookups for efficient access to a map table.

12 In a hash table lookup design, decision block 503 in Fig. 5 could be a hashing  
13 algorithm. Hashing can take different forms. One form could be to mask off all bits in a  
14 field except some bits; the unmasked bits could be either high, or low, or mid order bits.  
15 The unmasked bits are used as an index, as an approximation to get to the general area of  
16 the correct answer very quickly. An alternative hashing design would take all bits in the  
17 field but would fold them together to obtain a smaller number of bits, again to accomplish  
18 the very fast approximation objective. There are other hashing designs as well. In any of  
19 these hashing designs one can avoid an exhaustive search, entry by entry, using the  
20 distilled frame header and each entry set of fields in the map table, as earlier presented.  
21 A hashing approach in connection with such a table would provide an output advising  
22 whether or not any matches existed in the sampled subset of the table – and if not then the  
23 search could move on quickly to the next sampling of entries.

1           The present embodiments are therefore to be considered in all respects as  
2     illustrative and not restrictive. For example, the invention need not use a fibrechannel  
3     switch; any functionality that is the equivalent of such a switch, such as Infiniband could  
4     be utilized with the present invention. The scope of the invention is indicated, therefore,  
5     by the appended claims rather than by the foregoing description, and all changes which  
6     come within the meaning and range of equivalency of the claims are therefore intended to  
7     be embraced therein.

1

2 What is claimed is:

3 1. A storage system for storing data for at least one host computer, said system

4 comprising:

5 a plurality of disk drives for storing and supplying said data;

6 a switch having a plurality of input and output ports, said switch being connected

7 between said plurality of disk drives and said at least one host computer for at least

8 connecting one of said input ports on which said data was received to one of said output

9 ports;

10 an aggregator connected to said switch for at least managing operation of said

11 plurality of disk drives; and,

12 operation coordinating logic operatively coupled to coordinate operation of said

13 plurality of disk drives, said switch, and said aggregator in a manner to control flow of

14 certain of said data between said at least one host computer and said plurality of disk

15 drives to be through said switch and not through said aggregator and in a manner which

16 does not change the operation of said at least one said host computers.

17

18 2. The storage system of claim 1 and wherein said switch is a fibrechannel switch

19 and said operation coordinating logic utilizes protocol including fibrechannel protocol.

20

21 3. The storage system of claim 2 and wherein said fibrechannel protocol includes

22 fibrechannel FC2 frame headers.

23

1           4. The storage system of claim 3 and wherein each of said frame headers has a  
2     predetermined set of information fields.

3  
4           5. The storage system of claim 4 and wherein said fields include but are not  
5     limited to destination ID, source ID, sequence ID, sequence count, originator's exchange  
6     ID, and respondent's exchange ID.

7  
8           6. The storage system of claim 5 and wherein said operation-coordinating logic  
9     includes mapping logic for generating a mapping command designating said host  
10    computer as said source ID, said aggregator as said destination ID and a first particular  
11    said originator ID, and further having a mapped destination ID which designates a  
12    particular one of said plurality of disk drives which is connected to a particular one of  
13    said output ports.

14  
15          7. The storage system of claim 6 and wherein said operation-coordinating logic  
16     includes unmapping logic for generating an unmapping command designating said host  
17     computer as said source ID, said aggregator as said destination ID and said first particular  
18     said originator ID whereby the effect of the operation of said mapping command is  
19     neutralized.

20  
21          8. The storage system of claim 6 and wherein said operation-coordinating logic  
22     includes proxy logic for generating a proxy command having said aggregator as said  
23     source ID, said particular one of said plurality of disk drives as said destination ID, and

1 said first particular originator ID, and further having a proxy destination ID which  
2 designates a particular said at least one host computer.

3  
4 9. The storage system of claim 7 and wherein said operation-coordinating logic  
5 includes transfer-ready logic for generating a transfer-ready command having said  
6 aggregator as said source ID, said particular said at least one host computer as said  
7 destination ID, and said first particular said originator ID,.

8  
9 10. The storage system of claim 7 and wherein said particular said at least one  
10 host computer generates data having said at least one host computer as said source ID,  
11 said aggregator as said destination ID, and said first particular said originator ID.

12  
13 11. The storage system of claim 5 including logic for selecting said certain of  
14 said data to obtain particular data words and wherein each of said words is operated upon  
15 by said operation-coordinating logic in a manner to steer said each of said such words  
16 directly to a particular one of said plurality of disk drives.

17  
18  
19 12. A computer data storage system wherein said data is grouped in frames,  
20 comprising:

21 a plurality of disk drives for storing and retrieving said data;

22 an aggregator for managing operation of said plurality of disk drives;

1           each of said frames including a header containing binary fields designating  
2   parameters including at least destination ID, said header being associated with that  
3   portion of said data contained within said each of said frames; and,  
4           a switch connected between said computer, said disk drives, and said aggregator  
5   for both controllably selecting certain ones of said frames and flowing said portion of  
6   said data grouped in said certain ones and having said aggregator as said destination ID  
7   directly between said computer and said plurality of disk drives, whereby data transfer  
8   through said aggregator is avoided for said certain ones of said frames.

9  
10           13. The system of claim 12 and wherein said switch includes switch control logic  
11   arranged to be commanded by said aggregator to selectively switch said certain ones of  
12   said frames directly between said computer and said plurality of disk drives and all other  
13   of said frames indirectly therebetween through said aggregator.

14  
15           14. The system of claim 13 and wherein said switch control logic includes a  
16   frame header field selector, an input frame header buffer, and a map table.

17  
18           15. The system of claim 14 and wherein said frame header field selector is a  
19   frame header mask.

20  
21  
22           16. In a computer system including a plurality of disk drives for storing and  
23   retrieving data grouped in frames each one of said frames having a frame header

1 including an original destination ID, and an aggregator normally arranged to be in the  
2 path of said frames flowing between said computer and said plurality of disk drives, a  
3 method for enhancing the transfer of said data between said computer and said plurality  
4 of disk drives comprising:

- 5 a. establishing a frame header field selector designating only information  
6 relevant to said method;
- 7 b. receiving each one of said frames including its respective said frame  
8 header from said computer;
- 9 c. using said frame header field selector with each said respective said  
10 frame header to obtain a distilled frame header;
- 11 d. establishing a map table containing sets of frame header fields each one  
12 of said sets of frame header fields corresponding to a proxy destination ID of one of said  
13 plurality of disk drives;
- 14 e. searching said map table for a match between said distilled frame  
15 header and at least said one of said sets of frame header fields to obtain a matched frame  
16 header field set; and,
- 17 f. substituting said proxy destination ID in place of said original  
18 destination ID in said frame header of each one of said frames corresponding respectively  
19 to said matched frame header field set, whereby said each one of said frames is forwarded  
20 directly to said particular one of said plurality of disk drives and not via said aggregator.

1           17. The method of claim 16 including the operation of forwarding each of said  
2 frames other than said frames corresponding respectively to said matched frame header  
3 field set to its respective said original destination ID via said aggregator.

4  
5           18. The method of claim 16 and wherein the operation of searching said map  
6 table utilizes a hash algorithm.

7  
8  
9           19. In a computer system employing network-attached storage having both disk  
10 drives and a disk-drive-aggregator attached to said network, a method for enhancing the  
11 transfer of data between said computer and said storage comprising:

12           (a) said aggregator determining if overall performance of said computer system  
13 shall be increased if said data should be transferred between said computer and said disk  
14 drives either directly through said network or indirectly through said network and said  
15 aggregator;

16           (b) if the determination made in step (a) is indirectly through said network and  
17 said aggregator, then routing said data between said computer and said disk drives  
18 through said network and said aggregator; and,

19           (c) if the determination made in step (a) is directly through said network, then  
20 sending said data between said computer and said disk drives through said network but  
21 not through said aggregator.

1           20. In a computer system employing network-attached storage having both disk  
2 drives and a disk-drive aggregator attached to said network, a method for enhancing the  
3 transfer of data between said computer and said storage comprising:

4           transferring said data between said computer and said disk drives directly through  
5 said network, said data otherwise normally transferring indirectly through said network,  
6 by achieving particular cooperation among said aggregator, said network, and said disk  
7 drives.

8  
9           21. The method of claim 20 and wherein said transferring is performed in a  
10 manner not perceptible to said computer.

11  
12  
13           22. In a computer system including a plurality of disk drives for storing and  
14 retrieving data grouped in frames each one of said frames having a frame header  
15 including an original destination ID, and an aggregator normally arranged to be in the  
16 path of said frames flowing between said computer and said plurality of disk drives,  
17 apparatus for enhancing the transfer of said data between said computer and said plurality  
18 of disk drives comprising:

19           a. means for establishing a frame header field selector designating only  
20 information relevant to said method;

21           b. means for receiving each one of said frames including its respective  
22 said frame header from said computer;

1                   c. means for using said frame header field selector with each said  
2   respective said frame header to obtain a distilled frame header;  
3                   d. means for establishing a map table containing sets of frame header  
4   fields each one of said sets of frame header fields corresponding to a proxy destination ID  
5   of one of said plurality of disk drives;  
6                   e. means for searching said map table for a match between said distilled  
7   frame header and at least said one of said sets of frame header fields to obtain a matched  
8   frame header field set; and,  
9                   f. means for substituting said proxy destination ID in place of said  
10   original destination ID in said frame header of each one of said frames corresponding  
11   respectively to said matched frame header field set, whereby said each one of said frames  
12   is forwarded directly to said particular one of said plurality of disk drives and not via said  
13   aggregator.

14  
15           23. The apparatus of claim 22 including means for forwarding each of said  
16   frames other than said frames corresponding respectively to said matched frame header  
17   field set to its respective said original destination ID via said aggregator.

18  
19           24. The apparatus of claim 23 and wherein means for searching said map table  
20   includes means for utilizing a hash algorithm.

21

22

1           25. A computer product for use on a computer system including a plurality of  
2 disk drives for storing and retrieving data grouped in frames each one of said frames  
3 having a frame header including an original destination ID, and an aggregator normally  
4 arranged to be in the path of said frames flowing between said computer and said  
5 plurality of disk drives, and a computer usable medium having computer readable  
6 program code thereon for enhancing the transfer of said data between said computer and  
7 said plurality of disk drives comprising:

8           a. program code for establishing a frame header field selector designating  
9 only information relevant to said method;

10           b. program code for receiving each one of said frames including its  
11 respective said frame header from said computer;

12           c. program code for using said frame header field selector with each said  
13 respective said frame header to obtain a distilled frame header;

14           d. program code for establishing a map table containing sets of frame  
15 header fields each one of said sets of frame header fields corresponding to a proxy  
16 destination ID of one of said plurality of disk drives;

17           e. program code for searching said map table for a match between said  
18 distilled frame header and at least said one of said sets of frame header fields to obtain a  
19 matched frame header field set; and,

20           f. program code for substituting said proxy destination ID in place of said  
21 original destination ID in said frame header of each one of said frames corresponding  
22 respectively to said matched frame header field set, whereby said each one of said frames

1 is forwarded directly to said particular one of said plurality of disk drives and not via said  
2 aggregator.

3  
4 26. The computer program product of claim 25 including program code for  
5 forwarding each of said frames other than said frames corresponding respectively to said  
6 matched frame header field set to its respective said original destination ID via said  
7 aggregator.

8  
9 27. The apparatus of claim 26 and wherein program code for searching said map  
10 table includes program code for utilizing a hash algorithm.

11  
12  
13 28. A computer program product for use in a computer system employing  
14 network-attached storage having both disk drives and a disk-drive-aggregator attached to  
15 said network, and a computer usable medium having computer readable program code  
16 thereon for enhancing the transfer of data between said computer and said storage  
17 comprising:

18 (a) said aggregator including program code for determining if overall  
19 performance of said computer system shall be increased if said data should be transferred  
20 between said computer and said disk drives either directly through said network or  
21 indirectly through said network and said aggregator;

1 (b) if the determination made in operation (a) is indirectly through said network  
2 and said aggregator, then program code for routing said data between said computer and  
3 said disk drives through said network and said aggregator; and,

4 (c) if the determination made in operation (a) is directly through said network,  
5 then program code for sending said data between said computer and said disk drives  
6 through said network but not through said aggregator.

7  
8  
9 29. A computer program product for use in a computer system employing  
10 network-attached storage having both disk drives and a disk-drive aggregator attached to  
11 said network, and a computer usable medium having computer readable program code  
12 thereon for enhancing the transfer of data between said computer and said storage  
13 comprising:

14 program code for transferring said data between said computer and said disk  
15 drives directly through said network, said data otherwise normally transferring indirectly  
16 through said network, by achieving particular cooperation among said aggregator, said  
17 network, and said disk drives.

18  
19 30. The computer program product of claim 29 and wherein both said program  
20 code for transferring and the results of the running of said program code for transferring  
21 are not perceptible by said computer.

**ABSTRACT OF THE DISCLOSURE**

There is disclosed apparatus and methodology for enhancing computer system data transfer when writing to network attached storage systems employing FC-2 fibrechannel protocol by dynamically reconfiguring a fibrechannel switch in response to map/unmap command controls issued by a disk drive aggregator. The reconfiguration involves fabrication of a dynamic map table having sets of fibrechannel FC-2 header fields and their corresponding new or proxy destination IDs (which correspond to the switch's output ports), and fabrication of both an input frame header buffer for temporary storage purposes and a frame header field selector (which can be a frame header mask) containing only relevant information. The input frame header is temporarily stored in the buffer and the field selector is used to obtain a "distilled" input header which is compared with the dynamic map table of stored header fields to obtain a match. If one of the sets of header fields matches the distilled input header, its corresponding proxy destination or source ID is substituted into the corresponding FC-2 input frame header's destination ID field, whereby write command data transfers are accomplished between host computer and a particular disk drive directly, avoiding the aggregator and latency otherwise introduced by the aggregator. Similar disclosure is provided for read command data.

## **DECLARATION AND POWER OF ATTORNEY**

We, the below named inventors, hereby declare that:

Our residences, post office addresses, and citizenships are as stated below next to our respective names.

We believe we are the original, first, and joint inventors of the subject matter which is claimed and for which a patent is sought on the invention entitled **SWITCH-BASED ACCELERATION OF COMPUTER DATA STORAGE EMPLOYING AGGREGATIONS OF DISK ARRAYS**, the specification of which is attached hereto.

We hereby state that we have reviewed and understand the contents of the above identified specification, including the claims.

We acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, Section 1.56(a).

We hereby appoint the following attorneys:

Joel Wall, Reg. No. 25, 648  
Robert L. Dulaney, Reg. No. 28,071  
John M. Gunther, Reg. No. 26,175  
Leanne J. Fitzgerald, Reg. No. 40,606  
Krishnendu Gupta, Reg. No. 37,977  
Penelope Wilson, Reg. No. 29,751

to prosecute this application and transact all business in the Patent and Trademark Office connected therewith.

We request that all correspondence be directed to:

**EMC Corporation  
Law Department  
35 Parkwood Drive  
Hopkinton, MA 01748**

**ATTENTION: ROBERT L. DULANEY**

and all telephone calls be directed to:

**JOEL WALL (508)-435-4432**
